## 6 Signature Similarity

### 6.1 Introduction

As we have explained it in sect. 3.8 the introduction of an appropriate signature is a challenging problem. When a decision on the choice of image signatures has been made, how to use them for accurate image retrieval is the next concern. There is a large number of fundamentally different solutions proposed in recent years. Some of the key motivating factors behind the design of the proposed image similarity measures can be summarized as follows:

- agreement with semantics;
- robustness to noise (invariant to perturbations);
- computational efficiency (ability to work in real time and in large scale);
- invariance to background (allowing region-based querying); and
- local linearity (i.e., following triangle inequality in a neighbourhood).

The various techniques can be grouped according to design philosophy as follows:

- treating features as vectors, non-vector representations, or ensembles;
- using region-based similarity, global similarity, or a combination of both;
- computing similarities over linear space or nonlinear manifold;
- considering the role played by image segments in similarity computation;
- using stochastic, fuzzy, or deterministic similarity measures;
- use of supervised, semi-supervised, or unsupervised learning.

Some of those methods have been discussed in [41], but here, we focus on some of the more recent approaches to image similarity computation.

As we have observed in sect. 5.2.1, there are many metrics fulfilling all metric requirements. However, in real life the symmetry is questionable, for example, the way up a hill and down a hill takes different time. A similar situation is when we compare images. We can imagine various criteria, for instance, the number of particular elements or segments which constitute a query. Hence, when we select

as a query an image among the previous matching images, we obtain a different set of matching images because the symmetry is incomplete.

In such a situation a quasi-metric may be needed. A quasi-metric is defined as a function that satisfies the previously mentioned axioms for a metric without symmetry:

$$d(x,y) \neq d(y,x). \quad (6.1)$$

This notion is more often used in practice than in mathematics, and that is why it is sometimes called a semi-metrics [163].

## 6.2 Hausdorff Distance

As we have mentioned in the previous sections (3.8, 5.2.1 and 5.5), a feature value can be global, i.e. taking in to account all the pixels in the image, and local only for some segments.

An image signature can be seen as the form of a weighted set of feature vectors  $\{(z_1, p_1), (z_2, p_2), \dots, (z_n, p_n)\}$ , where  $z_i$ 's are the feature vectors and  $p_i$ 's are the corresponding weights assigned to them. Let us denote two signatures by:

$$I_m = \{(z_1^{(m)}, p_1^{(m)}), (z_2^{(m)}, p_2^{(m)}), \dots, (z_{n_m}^{(m)}, p_{n_m}^{(m)})\}, \quad m = 1, 2. \quad (6.2)$$

A natural approach to defining a region-based similarity measure is to match  $z_i^{(1)}$ 's with  $z_j^{(2)}$ 's and then to combine the distances between these vectors as a distance between sets of vectors [164], which is not as intuitive as between individual vectors.

One approach to the matching images  $I_1$  and  $I_2$  [164] is an assignment of a weight  $s_{i,j}$  to every pair  $z_i^{(1)}$  and  $z_j^{(2)}$ ,  $1 \leq i \leq n_1$ ,  $1 \leq j \leq n_2$ , so that the weight  $s_{i,j}$  indicates the significance of associating  $z_i^{(1)}$  with  $z_j^{(2)}$ . One motivation for the soft matching is to reduce its impact on retrieval of inaccurate segmentation. The weights are subject to constraints, the most common ones being  $\sum_i s_{i,j} = p_j^{(2)}$  and  $\sum_j s_{i,j} = p_i^{(1)}$ . Once the weights are determined, the distance between  $I_1$  and  $I_2$  is aggregated from the pair-wise distances between individual vectors.

Specifically:

$$D(I_1, I_2) = \sum_{i=1}^{n_1} \sum_{j=1}^{n_2} s_{i,j} d(z_i^{(1)}, z_j^{(2)}) \quad (6.3)$$

where the vector distance  $d(\cdot, \cdot)$  can be defined in diverse ways depending on the system.

One heuristic to decide the matching weights  $s_{i,j}$  for the pair  $(z_i^{(1)}, z_j^{(2)})$  is to seek  $s_{i,j}$ 's, such that  $D(I_1, I_2)$  in eq. (6.3) is minimized, subject to certain constraints on  $s_{i,j}$ . Suppose  $\sum_i p_i^{(1)} = 1$  and  $\sum_j p_j^{(2)} = 1$ . This can always be made true by the normalization, as long as there is no attempt to assign one image an overall higher significance than the other.

In practice,  $p_i^{(1)}$ 's (or  $p_j^{(2)}$ 's) often correspond to probabilities and automatically yield unit sum. Since  $p_i^{(1)}$  indicates the significance of region  $z_i^{(1)}$  and  $\sum_j s_{i,j}$  reflects the total influence of  $z_i^{(1)}$  in the calculation of  $D(I_1, I_2)$ , it is natural to require  $\sum_j s_{i,j} = p_i^{(1)}$  for all  $i$ , and similarly  $\sum_i s_{i,j} = p_j^{(2)}$ , for all  $j$ . Additionally, we have the basic requirement  $s_{i,j} \geq 0$  for all  $i,j$ . The definition of the distance is thus:

$$D(I_1, I_2) = \min_{s_{i,j}} \sum_{i=1}^{n_1} \sum_{j=1}^{n_2} s_{i,j} d(z_i^{(1)}, z_j^{(2)}), \quad (6.4)$$

This distance is precisely the Mallows distance in the case of discrete distributions [165], [166].

Other matching methods include the Hausdorff distance, which is asymmetric. We present it here for sets and show how to make more general for vectors.

**Definition 6.1.** (Hausdorff metric) [167]

Let  $(X, \rho)$  be a metric space and  $C(X) \subseteq X$  be a space of non-empty, closed and bounded subsets of  $X$ . Let  $N_\varepsilon(A) = \bigcup_{x \in A} B_\varepsilon(x)$  be the cover of  $A \in X$  by open  $\varepsilon$ -balls

$B_\varepsilon(x) = \{y \in X : \rho(x, y) < \varepsilon\}$ , where  $A, B$  are two compact subsets of metric space  $X$ . Since  $B_\varepsilon(x)$  is a neighbourhood of  $x$ , then  $N_\varepsilon(A)$  is a neighbourhood of  $A$  according to the definition of natural topology in metric spaces. The Hausdorff distance between  $A$  and  $B$  is defined as the smallest  $\varepsilon$ -neighbourhood of  $A$  which covers  $B$  and the other way round (see Fig. 6.1). On the other hand, the direct Hausdorff distance between  $A$  and  $B$ ,  $d_H^\triangleright(A, B)$  can be expressed as the maximum taken over from the collection of minimum distances between elements of sets  $A$  and  $B$ .

In the case of feature vectors, where every  $z_i^{(1)}$  is matched to its closest vector in  $I_2$ , say  $z_{i'}^{(2)}$ , the distance between  $I_1$  and  $I_2$  is the maximum among all  $d(z_i^{(1)}, z_{i'}^{(2)})$ . The Hausdorff distance by default is asymmetrical, hence in order to make it symmetrical additional computing must be done: the distance with the reversed role of  $I_1$  and  $I_2$  needs to be calculated and the larger of the two distances is selected:

$$D_H(I_1, I_2) = \max \left\{ \max_i \min_j d(z_i^{(1)}, z_j^{(2)}), \max_j \min_i d(z_j^{(2)}, z_i^{(1)}) \right\} \quad (6.5)$$

The Hausdorff distance is used for image retrieval in [168].

**Fig. 6.1.** Illustration of the asymmetric Hausdorff distance between sets  $A$  and  $B$ :  $d_H(A, B) = \epsilon$  and sets  $B$  and  $A$ :  $d_H(B, A) = \epsilon$ .

### 6.3 Signature Quadratic Form Distance

From eq. (6.2) we can notice that carrying out feature clustering individually for each data object reflects aggregation of feature distribution in a better way than any feature histogram. However, feature histograms are a special case of feature signatures whose centroids stay the same for the whole database and the information about objects is reflected only via weights, which results in a limitation of object representation.

#### **Definition 6.2** (Feature signature [169])

Let  $FS \subseteq R^k$  be a feature space and  $C = C_1, \dots, C_k$  be a local clustering of the features  $f_1, \dots, f_n \in FS$  of object  $o_{ij}$ . Then a feature signature  $S^o$  of length  $M^i$  can be defined as a set of tuples from a  $FS \times R^+$ , such as:

$$S^o = \{(c_k^o, w_k^o), k = 1, \dots, M\}. \quad (6.6)$$

where:  $c_k^o = \frac{\sum_{f \in c_k} f}{|c_k|}$  is a centroid of similar objects  $o_{ij}$  of image  $I_i$  and  $w_k^o = \frac{|c_k|}{n}$  is its weight.

It means that a feature signature  $S^o$  of object  $o_{ij}$  is a set of centroids  $c_k^o \in FS$  with the corresponding weights  $w_k^o \in R^+$  (see Fig. 6.2 (a)).

By this approach, Beecks et al. [169] aggregated the objects' location in the feature space which is substituted only by grouping similar feature values in

signature and histogram form. They proposed seven basic features: two coordinates, three components of colour and two texture descriptors.

**Definition 6.3** (Signature Quadratic Form Distance [169])

If  $S^o = \{\{c_k^o, w_k^o\}, k = 1, \dots, M\}$  and  $S^q = \{\{c_k^q, w_k^q\}, k = 1, \dots, N\}$  are two feature signatures, then the Signature Quadratic Form Distance (SQFD) between  $S^o$  and  $S^q$  is defined as:

$$SQFD(S^o, S^q) = \sqrt{(w_o | -w_q)A(w_o | -w_q)^T} \tag{6.7}$$

where:  $A \in R^{(M+N) \times (M+N)}$  is the similarity matrix,  $w_q = (w_1^q, \dots, w_m^q)$  and  $w_o = (w_1^o, \dots, w_n^o)$  are weight vectors and  $(w_o | -w_q) = (w_1^o, \dots, w_n^o, -w_1^q, \dots, -w_m^q)$ .

**Fig. 6.2** (a) Two feature signatures with their centroids and weights. (b) The illustration of the structure of similarity matrix A for two signatures  $S^o$  and  $S^q$ , according to Beeks et al. [169].

The similarity matrix **A** can be constructed assuming that there exists a similarity function  $f : FS \times FS \rightarrow R$ . The  $a_{k,l}$  components of **A** are calculated as follows:

$$a_{k,l} = f(c_k^o, c_l^q) = \frac{1}{1+d(c_k^o, c_l^q)} = \frac{1}{1+[(c_{k,x}^o - c_{l,x}^q)^2 + (c_{k,y}^o - c_{l,y}^q)^2]} \tag{6.8}$$

where:  $k, l = 1, \dots, N+M$ .

Fig. 6.3 and Fig. 6.4 present matching for two queries created by the user in the Hybrid Sematic System (HSS) (see sect. 9.9), computed according to the signature quadratic form distance (cf. (6.7)).

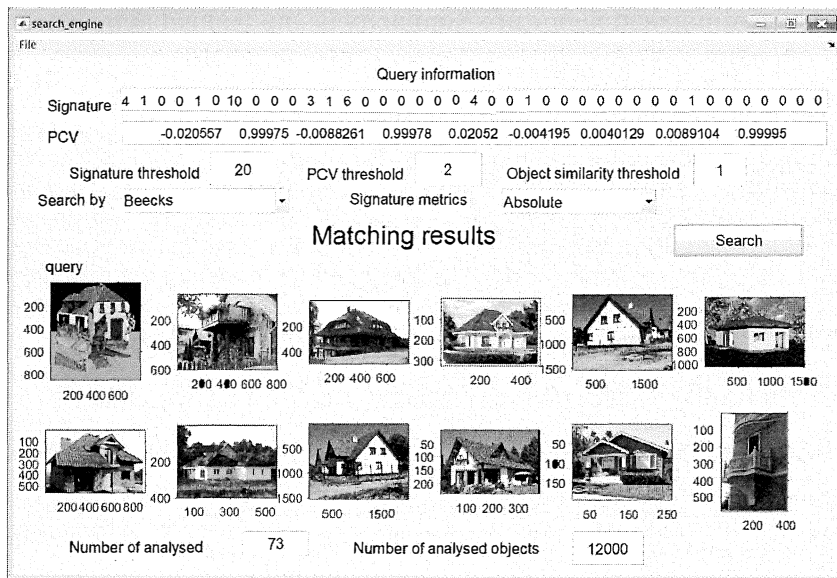

Fig. 6.3 Matching results for signature quadratic form distance for query 1.

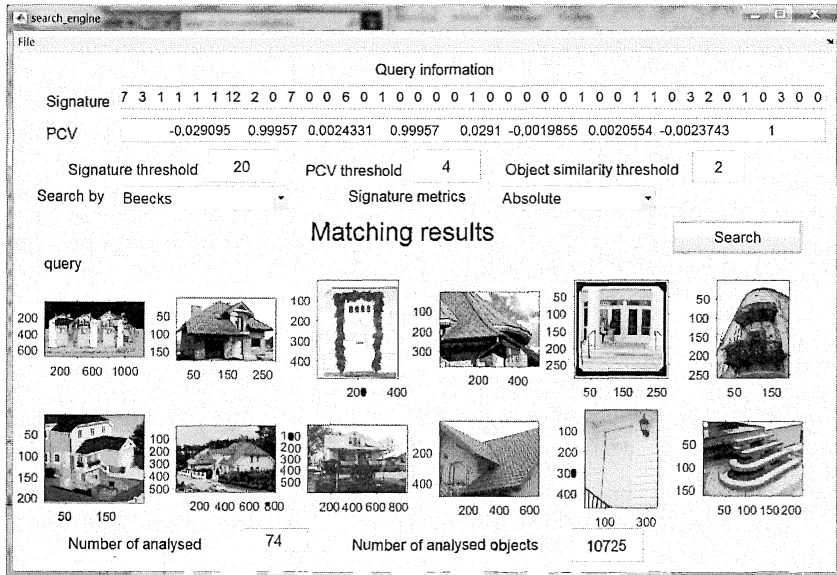

Fig. 6.4 Matching results for signature quadratic form distance for query 2.

## 6.4 Asymmetrical Signature Similarity in the Hybrid Semantic System

In the hybrid semantic system [170], at the first stage, objects  $o_{ij}$  are extracted from an image  $I_i$  based on low-level features (as it has been described in sect.4.2.4). These features are used for object classification. Additionally, the objects' mutual spatial relationship is calculated based on the centroid locations and angles between vectors connecting them, with an algorithm proposed by Chang and Wu [161] and later modified by Guru and Punitha [162], to determine the first three principal component vectors (PCV $_{oi}$ ,  $i=1, \dots, 3$  for each object  $o_{ij}$ ). Spatial object location in an image is used as the global feature [52] (compare sect. 5.5).

### Definition 6.4 (Image signature [170])

Let the query be an image  $I_q$  (cf. (5.22)), such as  $I_q = \{o_{q1}, o_{q2}, \dots, o_{qn}\}$ , where  $o_{ij}$  are objects. An image in the database is denoted as  $I_b$ ,  $I_b = \{o_{b1}, o_{b2}, \dots, o_{bm}\}$ . Let us assume that in the database there are, in total,  $M$  classes of the objects marked as  $L_1, L_2, \dots, L_M$ . Then, as the image signature  $I_i$  we denote the following vector:

$$\text{Signature}(I_i) = [\text{nobc}_{i1}, \text{nobc}_{i2}, \dots, \text{nobc}_{iM}] \quad (6.9)$$

where:  $\text{nobc}_{ik}$  are the number of objects  $o_{ij}$  of class  $L_k$  segmented from an image  $I_i$ . Note that the length of a signature is always the same and is equal to  $M$ .

Asymmetry is one of the most controversial properties of similarity. Like the Kullback-Leibler (K-L) divergence (see eq. (3.58)). and the Hausdorff distance our signature similarity is asymmetric. In order to answer the query  $I_q$ , we compare it with each image  $I_b$  from the database in the following way. A query image is obtained from the GUI, where the user constructs their own image from selected DB objects. First of all, we determine a similarity measure  $\text{sim}_{\text{sgn}}$  between the signatures of query  $I_q$  and image  $I_b$ :

$$\text{sim}_{\text{sgn}}(I_q, I_b) = \sum_i (\text{nob}_{q_i} - \text{nob}_{b_i}) \quad (6.10)$$

computing it as an equivalent of the Hamming distance between two vectors of their signatures (cf. (6.9)), such that  $\text{sim}_{\text{sgn}} \geq 0$  and  $\max_i (\text{nob}_{q_i} - \text{nob}_{b_i}) \leq \text{thr}$ ,  $\text{thr}$  is the limitation of the quantity of elements of a particular class by which  $I_q$  and  $I_b$  can differ. It means that we select from the DB images with objects in the same classes as the query. The above comparison is asymmetric because if we interchange the query and the image, we obtain a negative similarity value, that is:

$$\text{sim}_{\text{sgn}}(I_q, I_b) = - \text{sim}_{\text{sgn}}(I_b, I_q).$$

Then, the condition of non-negativity of similarity is incomplete. This fact is crucial from the semantic matching point of view because the human brain recognizes things in context with others.

Beecks et al. proposed only seven basic features, whereas we offered 45 features for a particular object, for example: moments of inertia and Zernike's moments [104].

In our adaptation of their method [171], a number of objects of a particular class were interpreted as weights. Object centroids represent locations of real, early segmented objects in the image space. Here, class centroids are situated in the geometrical centre among particular object centroids. We also use different methods to determine the similarity in these two approaches.

In our approach, there is the same number of classes for each image signature ( $N=M$ ), hence we decided to assume the length of vectors  $w_q$  and  $w_o$  equal to  $M$  which implies the size of a square matrix  $A_{[M \times M]}$ . Then the signature form distance (6.7) can be simplified to the form:

$$\text{SQFD}(S^o, S^q) = \sqrt{w_o A w_q^T} \quad (6.11)$$

and  $a_{k,l}$  components are computed only for  $k,l = 1, \dots, M$ , according to (6.8). Here, in Def. 2.3 and in our approach,  $S^q$  means a query signature, whereas  $S^o$  means image signatures in the database. The signature similarity, computed according to SQFD (cf. (6.11)), gives more information than the one computed according to  $\text{sim}_{\text{sgn}}$  (cf. (6.10)) which is seen in the results.

Results are presented in Table 9.1 and Table 9.2 in the sect. 9.9 where the search engine for the Hybrid Semantic System is described in detail.

## 6.5 Other Signature Similarities

The above-mentioned methods have been used so far, however, it has been observed lately that it is too ambitious to expect a single similarity measure to produce an effective, perceptually meaningful ranking of images or objects. As an alternative, attempts have been made to augment the effort with learning-based techniques.

Automatic learning of image similarity measures with the help of contextual information has been explored in Wu et al. [172]. In the case when a valid pairwise image similarity metric exists despite the absence of an explicit vectored representation in some metric space, *anchoring* can be used for ranking images [173]. Anchoring involves choosing a set of representative *vantage* images, and using the similarity measure to map an image into a vector. Suppose there exists a valid metric  $d(F_i, F_j)$  between each image pair, and a chosen set of  $K$  vantage images  $\{A_1, \dots, A_K\}$ . A *vantage space transformation*  $V_A: F \rightarrow R^K$  then maps each image  $F_i$  in the database with  $N$  objects to a vectored representation  $V_A(F_i)$  as follows:

$$V_A(F_i) = \langle d(F_i, A_1), \dots, d(F_i, A_K) \rangle, \quad \forall 1 \leq i \leq N \quad (6.12)$$

With the resultant vector embedding, and after similarly mapping a query image in the same space, standard ranking methods may be applied for retrieval. When images are represented as ensembles of feature vectors, or underlying distributions of the low level features, visual similarity can be ascertained by means of nonparametric tests such as Wald-Wolfowitz and K-L divergence. When images are conceived as bags of feature vectors corresponding to regions, multiple-instance multi-label learning (MIML) can be used for similarity computation [174].

## List of Figures

<b>Fig. 1.1</b> This chart from [2] shows the average number of image requests and the total image bytes over the last five years. ....	11
<b>Fig. 2.1</b> A young and old woman drawn by an anonymous German postcard designer, 1888.....	16
<b>Fig. 2.2</b> Example of the system answer to a query containing the word 'lamp'.....	17
<b>Fig. 2.3</b> Example of 3D visualization of results obtained from a CBIR system [19]. ....	18
<b>Fig. 2.4</b> 3D visualization of connections between users on Facebook Network FritWork THREE.js created by Saurin Shah [20].....	18
<b>Fig. 2.5</b> General CBIR architecture. ....	19
<b>Fig. 2.6</b> Example of an original image.....	24
<b>Fig. 2.7</b> The block diagram of the Hybrid Semantic System. ....	25
<b>Fig. 3.1</b> Two most often used image representations: raster and vector; a) vector representation, b) vector with colour filling, c) close-up of the vector representation, d) close-up of the raster representation. ....	27
<b>Fig. 3.2</b> Example of a vector image - used as a prompt in the GUI.....	27
<b>Fig. 3.3</b> The categories of texture describing methods.....	30
<b>Fig. 3.4</b> Gabor function, where a) the real part of the function and b) the imaginary part of the function [79]. ....	35
<b>Fig. 3.5</b> Examples of 2D Gabor functions for particular angles $\theta = n\pi K$ , where $K$ is the number of orientations. The outside windows present 2D Gabor filters, where $K = 9$ . The central contours correspond to the half-peak magnitude of the filter responses in the set of Gabor filters with the upper and lower centre frequency of interest: $\omega_h = 0.4$ and $\omega_l = 0.05$ , respectively, six orientations ( $K = 6$ ), and four scales ( $S = 4$ ), followed by [80]. ....	37
<b>Fig. 3.6</b> A function $f(x)$ and its projection onto two consecutive levels $V_{-1}$ and $V_0$ of the multiresolution analysis [83]. ....	38
<b>Fig. 3.7</b> An example of the dyadic Symmlet wavelets. A scale $j$ and location $k$ are presented for each wavelet $\psi_{j,k}$ on the right side [79]. ....	39
<b>Fig. 3.8</b> The real and imaginary parts of the Gabor wavelet for $\sigma=2$ and $\omega=3$ which are 'larger' than the example of the subset shown in Fig. 3.5 [79]. ....	39
<b>Fig. 3.9</b> A texture classifier flow chart based on the Gabor wavelet transformation (follows [80], [88]). ....	40
<b>Fig. 3.10</b> Distance maps of texture calculated based on the 2D FWT with Haar wavelets. a) The disposition of wavelet image coefficients $d_j^p$ where $j$ is a multiresolution level, and $a_j$ is an approximation at $j$ level. b) Horizontal wavelet coefficients presented along the 100 <sup>th</sup> column of the image transform (for the Haar wavelet, where $j = 1$ ). c) Cross-section through the 100 <sup>th</sup> column of the distance map for positive horizontal wavelet coefficients. d) Cross-section through the 100 <sup>th</sup> column of the distance map	

for negative horizontal wavelet coefficients. e) Original image of a roof segment (the segment was separated from the whole image based on our colour algorithm (cf. subsect. 4.2.3). f) The red component of the original image. g) Distance map for negative horizontal wavelet coefficients $c_{H1}$ . h) Distance map for negative vertical wavelet coefficients $c_{V1}$ [49].	42
<b>Fig. 3.11.</b> The kind of edges (at the top), the first derivative of the edges (in the middle), the second derivative of the edges (at the bottom).	44
<b>Fig. 3.12</b> An example of edge detection. a) the original image, b) a layer segmented by clustering, c) an example of the Sobel method for the layer from b), d) an example of the Canny method for the layer from b).	46
<b>Fig. 3.13</b> A gradient vector flow (GVF) field for a U-shaped object. These vectors will pull an active contour towards the object boundary. (Follows: <i>Active Contours, Deformable Models, and Gradient Vector Flow</i> Chenyang Xu and Jerry L. Prince web page: <a href="http://www.iacl.ece.jhu.edu/static/gvf/">http://www.iacl.ece.jhu.edu/static/gvf/</a> )	48
<b>Fig. 3.14</b> Left: The original image. Right: Lines (green) found by the Hough transform.	49
<b>Fig. 3.15</b> The Hough transform space. White sinusoids represents lines visible in Fig. 3.14.	49
<b>Fig. 3.16</b> Shape describing methods [99].	51
<b>Fig. 3.17</b> The first Zernike base functions (followed Wikipedia).	52
<b>Fig. 3.18</b> The gradient magnitude and orientation at each point of a 4x4 set of samples (on the left) which are accumulated into orientation histograms with 8 bins each (in the middle). The key-points descriptor summarizes the contents over 4x4 subregions, as shown on the right, with the length of each arrow corresponding to the sum of the gradient magnitudes near that direction within the region. Peaks in the orientation histogram correspond to dominant directions of local gradients.	55
<b>Fig. 3.19</b> Scale invariant interest point detection: (Top) Initial multi-scale Harris points (selected manually) corresponding to one local structure [106].	57
<b>Fig. 3.20</b> Relations between different tools and the elaboration process of MPEG 7 [117].	62
<b>Fig. 3.21</b> Histogram intersection.	63
<b>Fig. 3.22</b> Transport of 'mass' from $H_j$ to $H_i$ .	65
<b>Fig. 3.23</b> Different types of image similarity measure and their mathematical formulations.	66
<b>Fig. 4.1</b> Example of application of the $K$ -means algorithm to the image from Fig. 2.6.	68
<b>Fig. 4.2</b> The way of labelling the set of pixels. Regions I, II, III show pixel brightness and the biggest value of the triple (R,G,B) determines its colour.	72
<b>Fig. 4.3</b> a) 12 cluster segmentation of Fig. 2. obtained by using the 'colour' algorithm, b) segmented objects presented in their average colours, c) the red layer consisted of three brightness regions, d), e) and f) extracted objects in natural colour: chimney, sky and railing, respectively.	74
<b>Fig. 4.4</b> Texture mosaic segmentation based on LBP [65].	74
<b>Fig. 4.5</b> Natural scene segmentation based on the texture according to the LBP [65].	75
<b>Fig. 4.6</b> Zero-crossings of the curvature.	76
<b>Fig. 4.7</b> Feature computation in the base model. Each layer has units covering three spatial dimensions ( $x/y/scale$ ), and at each 3D location, an additional dimension of feature type. The image layer has only one type of pixels, layers S1 and C1 have 4 types, and the upper layers have $d$ (many) types per location. Each layer is computed from the previous one by applying template matching or max pooling filters [130].	77
<b>Fig. 4.8</b> The left side shows an image region and its corresponding ellipse. The right side shows the same ellipse with the solid lines as the axes, the dots on the major axis as foci and the orientation which is the angle $\alpha$ between the horizontal dotted line and the major axis.	79
<b>Fig. 5.1</b> Example of a decision tree pruned to the 7 <sup>th</sup> level. We omitted the feature values in nodes for the clarity of the figure.	85
<b>Fig. 5.2</b> The optimal hyperplane and margins $M$ for an SVM trained with samples from two classes. The samples on the margin are called support vectors.	88
<b>Fig. 5.3</b> An ideal example of a fuzzy rule-based classifier $FC$ followed by Ishibuchi and Nojima [150].	90

<b>Fig. 5.4</b> Exemplification of a membership function calculated on the basis of statistical class parameters.....	93
<b>Fig. 5.5</b> Classification example [51]. The new element marked by the full green square is recognized as an arc among classes: arc, pillar and balcony. Membership functions are represented by solid colour lines and linguistic intervals are drawn in dashed lines. In this case, $x_1$ is orientation and $x_2$ the real part of Zernike's moment.....	94
<b>Fig. 5.6</b> Classification example [51]. The new element marked by the full green square is recognized as an arc among classes: arc, pillar and balcony. Membership functions are represented by solid colour lines and linguistic intervals are drawn in dashed lines. In this case, $x_1$ is area and $x_2$ the real part of Zernike's moment.....	95
<b>Fig. 5.7</b> The simplest 2D segment of a CNN. For each patch of samples - neurons $x_{[0,1]}$ (for pixels in image), $A$ computes features [158].....	96
<b>Fig. 5.8</b> $A$ - convolutional layer, $B$ - pooling layer.....	97
<b>Fig. 5.9</b> The three colour components RGB (red, green, blue) (bottom right) of the image of a dog are the inputs to a typical convolutional network. Information flows bottom up, with lower-level features acting as oriented edge detectors, and a score is computed for each image class in output [157]. The outputs of each layer (horizontally) are the inputs to the next layer. Each rectangular image is a feature map corresponding to the output for one of the learned features, detected in each of the image positions.....	98
<b>Fig. 5.10</b> General scheme of the deep learning classification process. The top flow presents a CNN training to perform an image classification task where the output of each convolved image is used as the input to the next layer. The bottom scheme shows the proper classification process (FC – Fully Connected layer) [160].....	98
<b>Fig. 5.11</b> The main stages of the PCV applied to determine the unique object spatial location in an image [52].....	101
<b>Fig. 6.1</b> Illustration of the asymmetric Hausdorff distance between sets $A$ and $B$ : $d_H(A,B) = \varepsilon$ and sets $B$ and $A$ : $d_H(B,A) = \varepsilon$ .....	105
<b>Fig. 6.2</b> (a) Two feature signatures with their centroids and weights. (b) The illustration of the structure of similarity matrix $A$ for two signatures $S^o$ and $S^q$ , according to Beeks et al. [169].....	106
<b>Fig. 6.3</b> Matching results for signature quadratic form distance for query 1.....	107
<b>Fig. 6.4</b> Matching results for signature quadratic form distance for query 2.....	107
<b>Fig. 7.1</b> For each year and class the plot presents the average precision at the object detection category obtained by the best-performing method in a particular class in a particular year [180] for participation in the Pascal VOC challenge.....	115
<b>Fig. 7.2</b> The database server model which supports our CBIR system.....	118
<b>Fig. 8.1</b> Query types [53].....	122
<b>Fig. 8.2</b> The main GUI window. An early stage of a terraced house query construction [53].....	124
<b>Fig. 8.3</b> Main components of the GUI. We can draw a contour of the bitmap (see a) and b)) and change the colour of an element (see c) and d)) [53].....	125
<b>Fig. 9.1</b> DB browsing based on visual similarity [218].....	128
<b>Fig. 9.2</b> A content-based image clustering method for public image repositories [223].....	130
<b>Fig. 9.3</b> Pathfinder networks of images organized by colour histogram [224].....	130
<b>Fig. 9.4</b> Schematic representation of the SOM ANN architecture.....	131
<b>Fig. 9.5</b> Retrieval process based on feature object representation [227].....	133
<b>Fig. 9.6</b> Point-to-point correspondence found by the SIFT descriptors.....	134
<b>Fig. 9.7</b> A hybrid ontology and content-based search engine architecture follows [230].....	136
<b>Fig. 9.8</b> Visual feature ontology [231].....	137
<b>Fig. 9.9</b> Flow chart of the algorithm follows [235].....	138
<b>Fig. 9.10</b> CBIR architecture with the relevance feedback (RF) mechanism.....	140
<b>Fig. 9.11</b> The full structure of our hybrid semantic CBIR system.....	143
<b>Fig. 9.12</b> Information flow in our hybrid semantic CBIR system.....	144

<b>Fig. 9.13</b> The method for object comparison, where $I_q$ – query and $I_b$ – an image from the DB.....	146
<b>Fig. 9.14</b> A main concept of the hybrid search engine. ....	147
<b>Fig. 9.15</b> An example of the Curvelet Lab system retrieval for our query. (Efficiency according to Curvelet Lab system).....	151
<b>Fig. 9.16</b> An example of the Curvelet Lab system retrieval for our query. (Efficiency according to Curvelet Lab system).....	152
<b>Fig. 11.1</b> Examples of images which remain open problems in CBIR.....	165
